INTERNATIONAL APPLICATION NO.	INTERNATIONAL FILING DATE	PRIORITY DATE CLAIMED
PCT/JP99/04206	04 August 1999 (4.08.99)	

TITLE OF INVENTION LASER MODULE AND OPTICAL HEAD

APPLICANT(S) FOR DO/EO/US NAKAMURA, SHIGERU; SHIGEMATSU, KAZUO and KAMIISADA, TOSHIMASA

Applicant herewith submits to the United States Designated/Elected Office (DO/EO/US) the following items and other information:

1. This is a **FIRST** submission of items concerning a filing under 35 U.S.C. 371.
2. This is a **SECOND or SUBSEQUENT** submission of items concerning a filing under 35 U.S.C. 371.
3. This is an express request to begin national examination procedures (35 U.S.C. 371(f)). The submission must include items (5), (6), (9) and (21) indicated below.
4. The US has been elected by the expiration of 19 months from the priority date (Article 31).
5. A copy of the International Application as filed (35 U.S.C. 371(c)(2))
 - a. is attached hereto (required only if not communicated by the International Bureau).
 - b. has been communicated by the International Bureau.
 - c. is not required, as the application was filed in the United States Receiving Office (RO/US).
6. An English language translation of the International Application as filed (35 U.S.C. 371(c)(2)).
 - a. is attached hereto.
 - b. has been previously submitted under 35 U.S.C. 154(d)(4).
7. Amendments to the claims of the International Application under PCT Article 19 (35 U.S.C. 371(c)(3))
 - a. are attached hereto (required only if not communicated by the International Bureau).
 - b. have been communicated by the International Bureau.
 - c. have not been made; however, the time limit for making such amendments has NOT expired.
 - d. have not been made and will not be made.
8. An English language translation of the amendments to the claims under PCT Article 19 (35 U.S.C. 371(c)(3)).
9. An oath or declaration of the inventor(s) (35 U.S.C. 371(c)(4)).
10. An English language translation of the annexes of the International Preliminary Examination Report under PCT Article 36 (35 U.S.C. 371(c)(5)).

Items 11 to 20 below concern document(s) or information included:

11. An Information Disclosure Statement under 37 CFR 1.97 and 1.98.
12. An assignment document for recording. A separate cover sheet in compliance with 37 CFR 3.28 and 3.31 is included.
13. A **FIRST** preliminary amendment.
14. A **SECOND or SUBSEQUENT** preliminary amendment.
15. A substitute specification.
16. A change of power of attorney and/or address letter.
17. A computer-readable form of the sequence listing in accordance with PCT Rule 13ter.2 and 35 U.S.C. 1.821 - 1.825.
18. A second copy of the published international application under 35 U.S.C. 154(d)(4).
19. A second copy of the English language translation of the international application under 35 U.S.C. 154(d)(4).
20. Other items or information:

International Publication No. WO01/11615
Information Disclosure Sheet Under 37 CFR 1.56 w/refs.
International Search Report w/refs.

PRELIMINARY AMENDMENT

Commissioner for Patents
Washington, D.C. 20231

August 20, 2001

Sir:

The following amendments and remarks are respectfully submitted in connection with the above-identified application.

IN THE SPECIFICATION:

Page 12, after line 20, insert the following paragraphs:

--Other aspects of the present invention include a laser module used for an optical head constituting an optical information recording and reproduction apparatus, which performs tracking servo to record and reproduce the information when an optical spot is radiated on an optical information medium, and including optical convergence means for converging laser beams into the optical spot on the optical information medium, the laser module, comprising a light source where each of semiconductor laser chips having a plurality of wavelengths is mounted on its surface, a

photodetecting element for receiving each of a plurality of the laser beams radiated from each of the laser chips, and a package for enclosing the light source and the photodetecting element, wherein the surface where a plurality of the semiconductor laser chips are mounted is substantially perpendicular to the tracking servo direction.

A laser module comprising a semiconductor plate, a mount surface for laser chips provided on the semiconductor plate, a plurality of semiconductor laser chips mounted on the mount surface for the laser chips, a reflection plane provided on the semiconductor plate for reflecting laser beams radiated from a plurality of the semiconductor laser chips, and a photodetecting element, which is provided on the semiconductor plate, for receiving the laser beams radiated from a plurality of the semiconductor laser chips, wherein the photodetecting elements are arranged at both sides of a plurality of the semiconductor laser chips in a direction where a plurality of the semiconductor laser chips are arranged.

A laser module comprising a package for enclosing the semiconductor plate, wherein the outline of the package in a plane perpendicular to a direction, where the laser beam is radiated from the package, has an approximate rectangular shape in a degree where its long direction and short direction can be distinguished, and a plurality of semiconductor laser chips and the photodetecting element are arranged in a direction of the short side of the package.

A laser module comprising a semiconductor plate, a mount surface for laser chips provided on the semiconductor plate, a plurality of semiconductor laser chips mounted on the mount surface for the laser chips, a reflection plane provided on the semiconductor plate for reflecting laser beams radiated from a plurality of the semiconductor laser chips, and a photodetecting element, which is provided on the semiconductor plate, for receiving the laser beams radiated from a plurality of the semiconductor laser chips, wherein the semiconductor plate includes a plurality of pads for electrically connecting with an external electronic circuit and a plurality of the pads are arranged along a side of the semiconductor plate parallel with a direction where a plurality of the semiconductor laser chips are arranged.

A laser module comprising a plurality of the lead wires for electrically connecting a package for enclosing the semiconductor plate with an external electronic circuit, wherein the outline of the package in a plane perpendicular to a direction, where the laser beam is radiated from the package, has the approximate rectangular shape in a degree where its long direction and short direction can be distinguished, and a plurality of the lead wires are arranged in a direction of the short side of the package.--

IN THE CLAIMS:

Please amend claims 1 and 6 as follows:

1. (amended) An optical information recording and reproduction apparatus, comprising:

a setting portion of an optical information medium;
a light source where a plurality of semiconductor laser
chips are mounted on an identical surface;

optical convergence means for converging each of a plurality of laser beams radiated from each of laser chips into an optical spot on said optical information medium when the optical information medium is set to said setting portion; and

tracking servo means for moving the optical convergence means in a tracking servo direction perpendicular to a track direction such that the optical spot accurately scans the track of the optical information medium.

wherein a direction of alignment of said plurality of semiconductor laser chips is substantially perpendicular to the tracking servo direction.

6. (amended) An optical head used in an optical information recording and reproduction apparatus that performs tracking servo to record and reproduces information when an optical spot is radiated on an optical information medium.

wherein the optical head comprises:

a light source on which each of semiconductor laser chips having a plurality of wavelengths is mounted on an identical surface; and

1000-40513X00

optical convergence means for converging each of a plurality of laser beams radiated from each of the laser chips on said optical information medium as the optical spot, and a direction of alignment of said plurality of semiconductor laser chips is substantially perpendicular to said tracking servo direction.

Please cancel claims 11-15 without prejudice or disclaimer of the subject matter thereof.

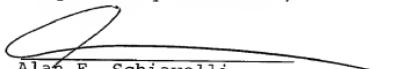

REMARKS

By the above amendment, the specification has been amended, claims 1 and 6 have been amended, and claims 11-15 have been canceled.

Examination of the application and favorable action thereof is respectfully requested.

Please charge any shortage in the fees due in connection with the filing of this paper, to Deposit Account No. 01-2135 (500.40513X00) and please credit any excess fees to such deposit account.

Respectfully submitted,

DESCRIPTION

LASER MODULE AND OPTICAL HEAD

TECHNICAL FIELD

The present invention relates to a laser module, an optical head or an optical information recording and reproduction apparatus that are used when 5 recording information to an optical information medium such as an optical disk or when reproducing the information from the optical information medium. More particularly, the present invention relates to a laser module, an optical head or an optical information 10 recording and reproduction apparatus that mounts a plurality of light sources.

:

BACKGROUND ART

In addition to smaller and thinner size, various kinds of functions are required to an optical 15 information recording and reproduction apparatus such as an optical disk drive or unit.

In a conventional normal optical disk unit using one light source, a high-speed data transfer is desired since information validation after the 20 information has been recorded is performed by rotating a disk again, which leads to a slow data transfer speed. In Japanese Patent Laid-Open 64-70936 gazette, a multi-beam type optical head is suggested in which

two semiconductor laser chips are arranged in an optical head in a opposing manner, two parallel beams are formed by the same collimating lens, the two beams are made to be incident to a focusing lens, two optical 5 spots are radiated on the same track on an optical disk surface, and the information recording and reproduction for the information validation are performed at a substantially same time. In the multi-beam type head, the two light sources perform the recording and the 10 reproduction for the recording validation, and thus the disk does not need to be rotated again for the recording validation. In the example of JP-A- 64- 70936, a high output laser beam source and an optical system having a high optical efficiency for radiating a 15 laser beam from the light source on the disk efficiently are necessary. On the other hand, the optical efficiency of the optical system may be low regarding a laser beam performing the reproduction of the information. Accordingly, a device that 20 accomplishes the high optical efficiency only for the leaser beam performing the information recording is sufficient.

Moreover, a requirement has been increasing in recent years that both of a CD-R (Compact Disk- 25 Recordable) that has spread as a writable optical disk and a DVD (Digital Versatile Disc/Digital Video Disc) developed as a writable optical disk in higher density need to be recorded/reproduced with the same small

optical head. Since a laser wavelength suitable for the recording/reproduction of the CD-R is approximately 780 nm while a laser wavelength suitable for the recording/reproduction of the DVD is approximately 660
5 nm, both of the laser beam source having the wavelength of 780 nm and the laser beam source having the wavelength of 660 nm needs to be mounted on the same optical head. For example, in JP-A-10-241189 and JP-A-
10-289468, small optical heads are suggested in which a
10 semiconductor laser chip for a compact disk having the wavelength of approximately 780 nm, a semiconductor laser chip for a DVD having the wavelength of approximately 660 nm and a photodetecting element are formed in a unit. Normally, beams having different
15 radiation points pass the different positions of the lens system. Similarly, in the optical heads, the beams radiated from the two semiconductor laser chips are made to be incident to the different positions of a focusing lens. Then, optical paths of the two beams
20 are unified by using a transmissive hologram (grating) in JP-A-10-241189 and synthesis means by a polarizable prism (birefringent plate) or a hologram in Japanese Patent Laid-Open 10-289468. Furthermore, Fig. 6 of JP-A-10-289468 and Fig. 3 of JP-A-10-261240 show that the
25 beam position from the laser beam source arranged outside an axis and the beam position from the laser beam source arranged on the axis are unified in the vicinity of the focusing lens by allowing the distance

between the laser beam source, the collimating lens and the focusing lens to be substantially equal.

DISCLOSURE OF THE INVENTION

However, the laser beam radiated from the
5 semiconductor laser chip does not have an even optical
intensity distribution but has the optical intensity
distribution having high intensity at the central
portion of the beam. Accordingly, even if the optical
paths of a plurality of the laser beams are unified as
10 in the foregoing example, the central position of the
optical intensity distribution of the laser beam is off
from the center of the focusing lens in the case where
the semiconductor laser chip is mounted in a tilted
manner. Thus, the optical efficiency of the optical
15 head system reduces. Therefore, in the optical head
and optical disk unit using a plurality of the
semiconductor laser beams for the information
recording, the arrangement of optical parts needs to be
decided such that the reduction of the optical
20 efficiency for each laser beam is minimized taking into
consideration the direction of an angle shift and its
accuracy that occurs when the semiconductor laser chip
is mounted.

Furthermore, the optical disk unit and the
25 like perform tracking servo in which the focusing lens
and the like is moved in the radius direction of the
optical disk such that the optical spot accurately

scans the track of the optical disk. Thus, the central position of the optical intensity distribution is off from the center of the focusing lens even by the tracking servo, and thus the optical efficiency of the
5 optical head system changes. Then, an optical head is necessary whose optical efficiency is hard to be changed due to the tracking servo. Accordingly, the arrangement of the optical parts needs to be decided such that the fluctuation of the optical efficiency for
10 each laser beam is minimized taking into consideration the direction of the focusing lens movement and the like for the tracking servo.

The object of the present invention is to solve the foregoing problems in the laser module and
15 the optical head or the optical information recording and reproduction apparatus that are used for recording the information to the optical information medium or reproducing the information by using a plurality of the laser beam sources, and to provide the laser module and
20 the optical head or the optical information recording and reproduction apparatus in which the optical efficiency reduction and change of each laser beam are minimum for the angle shift occurred when attaching the semiconductor laser chip or the focusing lens movement
25 for the tracking servo.

To achieve the foregoing objects, in the optical head that comprises: a plurality of the laser beam; optical convergence means such as the focusing

lens for converging a plurality of the laser beams
radiated from the laser beam sources into the optical
spot on the optical information medium such as the
optical disk; and tracking servo means such as a lens
5 actuator for moving the optical convergence means in a
tracking servo direction perpendicular to a track
direction such that the optical spot accurately scans
the track of the optical information medium, a first
aspect of the present invention is that a plurality of
10 the laser beam sources are a plurality of the
semiconductor laser chips and a mount surface for the
laser chips on which a plurality of the semiconductor
laser chips are mounted is arranged to be substantially
perpendicular to the tracking servo direction. Herein,
15 in the case where the optical path reflects and
refracts due to a reflection plane and a refraction
plane in the optical path from the laser beam sources
to the optical convergence means, the reflection plane
and the refraction plane can be removed to make the
20 optical path straight if the optical convergence is
substituted with an image formed by the reflection
plane and the refraction plane, and the image of the
optical convergence means can be projected in a space
same as that of the laser beam sources. The above-
25 described term "substantially perpendicular" means that
the mount surface for the laser chips is arranged to be
perpendicular to the tracking servo direction of the
image of the optical convergence means when the

reflection plane and the refraction plane are removed to project the image of the optical convergence means in the space same as that of the laser beam sources.

In a second aspect of the present invention,
5 the optical head comprises: a first reflection plane formed by etching or the like for reflecting the laser beam radiated from a plurality of the semiconductor laser chips; and a second reflection plane such as a mirror for guiding the laser beam from the first
10 reflection plane to the optical convergence means, in which the first reflection plane is formed on a plate such as silicon or the like that is same as the mount surface for the laser chips.

Further, in a third aspect of the present
15 invention, the optical information recording and reproduction apparatus in which the laser beams from the first reflection plane is made to be incident from the tracking servo direction to the second reflection plane, and a plurality of the semiconductor laser chips
20 are arranged in an inner plane direction parallel to an optical information medium plane.

Moreover, in a fourth aspect of the present invention, the optical information recording and reproduction apparatus in which the laser beams from
25 the first reflection plane is made to be incident from the track direction to the second reflection plane, and a plurality of the semiconductor laser chips are arranged in an inner plane direction perpendicular to

the optical information medium plane.

In a fifth aspect of the present invention is the laser module that consists of: a plurality of the semiconductor laser chips; photodetecting element that

5 receives the laser beams radiated from a plurality of the semiconductor laser chips; and a package that encloses a plurality of the semiconductor laser chips and the photodetecting element, and the optical head or the optical information recording and reproduction

10 apparatus using the laser module that consists of: the optical convergence means such as the focusing lens for converging the laser beams radiated from the laser module into the optical spot on the optical information medium such as the optical disk; and the tracking servo

15 means such as a lens actuator for moving the optical convergence means in a tracking servo direction perpendicular to the track direction such that the optical spot accurately scans the track of the optical information medium, in which the mount surface for the

20 laser chips on which a plurality of the semiconductor laser chips are mounted is arranged to be substantially perpendicular to the tracking servo direction. Herein, "substantially perpendicular" means as described above.

Further, in a sixth aspect of the present
25 invention, the mount surface for the laser chips for attaching a plurality of the semiconductor laser chips is provided on a semiconductor plate such as silicon where the photodetecting element is formed on the

surface, and the first reflection plane formed by etching or the like is provided for reflecting the laser beams radiated from a plurality of the semiconductor laser chips, and then the second 5 reflection plane such as the mirror is arranged for guiding the laser beams radiated from the laser module to the optical convergence means.

Still further, in a seventh aspect of the present invention, the optical information recording 10 and reproduction apparatus in which the laser beams from the first reflection plane is made to be incident from the tracking servo direction to the second reflection plane, and a plurality of the semiconductor laser chips are arranged in the inner plane direction 15 parallel to the optical information medium plane.

Still further, in a eighth aspect of the present invention, the optical information recording and reproduction apparatus in which the laser beams from the first reflection plane is made to be incident 20 from the track direction to the second reflection plane, and a plurality of the semiconductor laser chips are arranged in the inner plane direction perpendicular to the optical information medium plane.

Still further, a ninth aspect of the present 25 invention is the laser module that comprises: the semiconductor plate such as silicon; the mount surface for the laser chips provided on the semiconductor plate; a plurality of the semiconductor laser chips

mounted on the mount surface for the laser chips; the reflection plane formed by etching or the like provided on the semiconductor plate for reflecting the laser beams radiated from a plurality of the semiconductor
5 laser chips; the photodetecting element, which is provided on the semiconductor plate, for receiving the laser beams radiated from a plurality of the semiconductor laser chips; and the package having an approximate cubic shape whose length in a horizontal
10 direction is longer than that in a vertical direction and that radiates the laser beam in a thickness direction, the package having lead wires on both sides in a longitudinal direction as the horizontal direction and enclosing the semiconductor plate at its
15 substantially central position, in which the semiconductor plate is enclosed in the laser module such that a plurality of the semiconductor laser chips are arranged in a vertical direction perpendicular to the longitudinal direction as the horizontal direction
20 of the package.

Still further, a ninth aspect of the present invention is the laser module that comprises: the semiconductor plate; the mount surface for the laser chips provided on the semiconductor plate; a plurality
25 of the semiconductor laser chips mounted on the mount surface for the laser chips; the reflection plane provided on the semiconductor plate for reflecting the laser beams radiated from a plurality of the

semiconductor laser chips; and the photodetecting element, which is provided on the semiconductor plate, for receiving the laser beams radiated from a plurality of the semiconductor laser chips, in which the

5 photodetecting elements are arranged at both sides of a plurality of the semiconductor laser chips in a direction where a plurality of the semiconductor laser chips are arranged.

Still further, in a tenth aspect of the present invention, the laser module comprises the package for enclosing the semiconductor plate, in which the outline of the package in a plane perpendicular to a direction, where the laser beam is radiated from the package, has an approximate rectangular shape in a degree where its long direction and short direction can be distinguished, and a plurality of semiconductor laser chips and the photodetecting element are arranged in a direction of the short side of the package.

Still further, an eleventh aspect of the
20 present invention is the laser module that comprises:
the semiconductor plate; the mount surface for the
laser chips provided on the semiconductor plate; a
plurality of the semiconductor laser chips mounted on
the mount surface for the laser chips; the reflection
25 plane provided on the semiconductor plate for
reflecting the laser beams radiated from a plurality of
the semiconductor laser chips; and the photodetecting
element, which is provided on the semiconductor plate,

for receiving the laser beams radiated from a plurality of the semiconductor laser chips, in which the semiconductor plate includes a plurality of pads for electrically connecting with an external electronic circuit and a plurality of the pads are arranged along a side of the semiconductor plate parallel with a direction where a plurality of the semiconductor laser chips are arranged.

Still further, in a twelfth aspect of the present invention, the laser module comprises a plurality of the lead wires for electrically connecting the package for enclosing the semiconductor plate with the external electronic circuit, in which the outline of the package in a plane perpendicular to a direction, where the laser beam is radiated from the package, has the approximate rectangular shape in a degree where its long direction and short direction can be distinguished, and a plurality of the lead wires are arranged in a direction of the short side of the package.

In the following, the first embodiment of the present invention will be described by using Fig. 1 to Fig. 5.

Fig. 1 shows the basic constitution of the optical disk unit and the optical head using the present invention. Reference numeral 1 denotes the semiconductor plate where the photodetecting elements, 5 the electronic circuit and the like are formed on its surface, the laser chips and the like are mounted thereon, and silicon or the like is preferable, for example. In Fig. 1, the front surface of the semiconductor plate 1 cannot be seen actually because 10 it is arranged facing its rear surface to a viewer, but the drawing shows in a phantom state where the plate is seen from the rear surface to the front surface. 2 denotes the mount surface for the laser chips, which is formed by engraving the surface of the semiconductor 15 plate 1 in the depth of approximately 30 μm to 100 μm by etching processing or the like, and the mount surface for the laser chips 2 is parallel with the surface of the semiconductor plate 1. The arrow 3 shows the normal direction of the mount surface for the 20 laser chips 2. 4a denotes the semiconductor laser chip for the DVD, which radiates the laser beam 6a having the wavelength $\lambda_a = 660 \text{ nm}$, and 4b denotes the semiconductor laser chip for the CD-R, which radiates the laser beam 6b having the wavelength $\lambda_a = 780 \text{ nm}$. 25 The semiconductor laser chips 4a and 4b are adhered to the mount surface for the laser chips 2 by soldering or the like. 5 denotes the semiconductor mirror surface formed between the surface of the semiconductor plate 1

and the mount surface for the laser chips 2, which can be simultaneously formed with the mount surface for the laser chips by etching processing or the like. The laser beam 6a for the DVD, after radiated from the
5 semiconductor laser chip 4a to an upward direction of Fig. 1, is reflected by the semiconductor mirror surface 5, and becomes a parallel luminous flux by the collimating lens 10. 7 denotes the photodetecting element that obtains a focusing error detection signal,
10 8: the photodetecting element that obtains a tracking error detection signal and an information reproduction signal, 9: photodetecting element that monitors a light emission amount of the semiconductor laser chips 4a and 4b, and 7, 8 and 9 are severally formed on the surface
15 of the semiconductor plate 1. 11 denotes the mirror that radiates the laser beams 6a and 6b on an information medium. 12 denotes the composite element in which a polarization four-division grating and a quarter-wave plate are adhered into a unit, which is
20 arranged facing the four-division grating to the semiconductor laser chip. The polarization four-division grating is made of, for example, a birefringent plate optical crystal plate or a liquid crystal plate, which transmits an incident light
25 without diffraction when it is an ordinary light and functions as the grating when it is an extraordinary light. 13 denotes the focusing lens, and a lens with variable entrance pupil diameter, a lens added with a

hologram element on an incident side, a lens added with the hologram element and a zone groove on the lens surface of the incident side, or the like can be used so as to be suitable for both of the optical disk for 5 the DVD, which has a plate thickness of 0.6 mm, a working wavelength of 660 nm and a numerical aperture of 0.6, and the optical disk for the CD-R and CD, which has a plate thickness of 1.2 mm, a working wavelength of 780 nm and a numerical aperture of 0.5. 15 denotes 10 the foregoing optical disk for the DVD and optical disk for the CD-R and CD. 16 denotes the rotation center of the optical disk 15, the circle 17 in a dotted line show the track to which information is recorded, and 18 denotes the radius direction of the optical disk 15. 15 Since the track 17 is displaced to the direction of 18 by the rotation of the optical disk, the tracking servo is required to make the optical spot of the laser beams 6a and 6b track the track 17. Accordingly, although not shown in Fig. 1, the focusing lens 13 is displaced 20 by the lens actuator or the like shown in Fig. 9 in the tracking servo direction shown by the reference numeral 14 by the use of electromagnetic force. In this embodiment, a projected image in the tracking servo direction is reflected by the mirror 11 and the 25 semiconductor mirror 5 to unify the normal direction 3 of the mount surface for the laser chips 2. Specifically, the mount surface for the laser chips 2 for mounting the semiconductor laser chips 4a and 4b is

substantially perpendicular to the tracking servo direction 14.

In this embodiment, the laser beams 6a and 6b radiated from the semiconductor laser chips 4a and 4b, 5 in the case of being incident to the composite element 12 made of the polarization four-division grating and the quarter-wave plate, are incident to the composite element 12 as the ordinary light and transmit the polarization grading portion without diffraction, and 10 then forms a circular polarization. The laser beams 6a and 6b reflected by the optical disk become the extraordinary light by the quarter-wave plate of the composite element 12 and diffracted by the polarization four-division grading. Fig. 2 shows an example of the 15 grating pattern of the four-division grading of the composite element 12, which is divided into four areas by the boundary lines 21 and 22. The circle 20 shows the laser beam 6a or 6b that is separated into four pieces of + primary diffraction light and four pieces 20 of - primary diffraction light by the four-division grating.

Fig. 3 (a) shows the surface of the semiconductor plate 1 seen from the collimating lens 10 side. The eight pieces of quarter circles painted in 25 black shown by the reference numeral 32a show the laser beams of the wavelength λ_a , which are separated by the grating, and the eight pieces of quarter circles that are not painted shown by the reference numeral 32b show

the laser beams of the wavelength λ_b , which are separated by the grating. 7 denotes the photodetecting element for obtaining the focusing error detection signal that consists of eight strap type photodetecting elements 7a for receiving the laser beams 32a of the wavelength λ_a and eight strap type photodetecting elements 7b for receiving the laser beams 32b of the wavelength λ_b . A knife edge method (Foucault method) by the four-division beams is used as a focusing error detecting method, a signal for subtraction is obtained from an A terminal and a B terminal of the wire bonding pad 34 when the photodetecting elements are connected by the conductive thin film 33 such as aluminum as shown in the drawing. 8 denotes the photodetecting elements for obtaining the tracking error detection signal and the information reproduction signal, and the output signal of the four photodetecting elements 8 goes through the amplifiers to be output from D, E, F and G terminals of the pad 34. 9 is the photodetecting element for monitoring the emission amount of the semiconductor laser chips 4a and 4b, and the output signal of the photodetecting element 9 is output from a C terminal of the pad 34. The points 31a and 31b show the reflection positions of the laser beams 6a and 6b on the semiconductor mirror 5 surface, which are radiated from the semiconductor laser chips 4a and 4b. For example, if the grating pitch P of all four areas shown in Fig. 2 are equal, the directions of the

gratings to the vertical line 21 are $+\alpha$, $-\alpha$, $+3\alpha$ and -3α degrees, and the focal distance of the collimating lens is fc , the laser beam 32a of the wavelength λ_a separated by the grating is converged on the position
5 with the gap of 2α degrees from the center, on a circumference with a radius $R_a = fc * \lambda_a/P$ having the center on the point 31a. In the same manner, the laser beam 32b of the wavelength λ_b separated by the grating is converged on the position with the gap of 2α degrees
10 from the center, on a circumference with a radius $R_b = fc * \lambda_b/P$ having the center on the point 31b. Presuming that a light emission point gap D of the semiconductor laser chips 4a and 4b as the gap between the points 31a and 31b is substantially $D \approx fc * (\lambda_b - \lambda_a)/P$, the
15 convergence position of the laser beam of the wavelength λ_a and the convergence position of the laser beam of the wavelength λ_b can be substantially unified. Thus, the beams having the different wavelengths can commonly use the same photodetecting elements and
20 amplifiers, and not only the surface of the semiconductor plate 1 can be saved, that is, the surface can be smaller, but also the number of the wire bonding pads and the output wires can be reduced, which is effective in making the size of the package that
25 encloses the semiconductor plate 1 smaller.

Fig. 3(b) shows a section structure of the semiconductor plate 1 at the dotted line A-A' of Fig. 3(a). It is preferable that the semiconductor mirror 5

is formed at the angle of 45 degrees to the mount surface for the laser chips 2. For example, processing of the mirror surface of a silicon plate is based on anisotropic etching that when etching is performed to a
5 silicon (100) plane by an aqueous solution of potassium hydroxide series, the etching rate of a (111) plane relative to the (100) plane is slower by two digits, leading to the formation of a pyramid-shaped concave portions having a flat (111) plane as a slope. At this
10 point, since the angle of the (111) plane relative to the (100) plane is about 54 degrees, the silicon plate with an off-angle of about 9 degrees, for example, whose crystallographic axis is tilted to the surface, needs to be used in order to form the semiconductor
15 mirror of 45 degrees. However, the off-angle angle needs to be determined by taking into consideration the compatibility of semiconductor process for the photodetecting element and the electronic circuit formation as well. There are cases where the
20 semiconductor mirror 5 is off from 45 degrees and where the emission direction of the laser beams 6a and 6b is off from the perpendicular direction of the semiconductor plate 1.

Fig. 4(a) shows the structure of the package
25 41 enclosing the semiconductor plate 1, Fig. 4(b) shows the sectional view at the broken line A-A', and Fig. 4(c) shows the sectional view at the broken line B-B'.
42 are the lead wires connected with the pad 34 of the

semiconductor plate 1 with the bonding wires. In Fig. 4(c), the surface of the base 43 where the semiconductor plate 1 is mounted is tilted such that the emission direction of the laser beams 6a and 6b 5 becomes perpendicular to the glass cover 44. In the case where the base 43 is not mounted in a tilted state, the entire base 43 may be arranged in the tilted state such that the centerline of the optical intensity distribution of the laser beam emitted from the package 10 41 becomes parallel with the optical path. 44 denotes the glass cover for closing the semiconductor plate 1, and the reflection plane 45 is provided inside the glass cover 44 for reflecting the peripheral portion of the laser beams 6a and 6b. The photodetecting element 15 9 of the semiconductor plate 1 receives the reflected beam by the reflection plane 45 to obtain a signal for monitoring the emission amount of the semiconductor laser chips 4a and 4b.

Fig. 10(a) and 10(b) show the structure of 20 the optical disk unit, in which 10(a) is a plan view and 10(b) is a side view. 101 denotes the case of the optical disk unit. 102 denotes the motor mounted on the case 101 of the optical disk unit to rotate the optical disk 15 via the shaft 103. 104 denotes the 25 optical head where the package 41 enclosing the semiconductor plate 1 and the lens actuator 105 mounted with the focusing lens 13 are mounted. 106 denotes the access mechanism mounted on the optical head, and 107

denotes the rail mounted on the case 101 of the optical disk unit. The optical head 104 can move on the rail 107 by the access mechanism 106 in the radius direction of the disk 15. The collimating lens 10, the mirror 11 and the composite element 12 are inside of the optical head 104. The laser beam 6a or 6b radiated from the semiconductor laser chip 4a or 4b mounted on the package 41 is radiated from the optical head via the focusing lens 13 on the lens actuator 105, and radiated 5 on a rotating optical disk 15. The reflected beam is incident to the optical head via the focusing lens 13 again, a part of which is received by the photodetecting element 7 mounted on the package 41 to obtain the focusing error detection signal. Moreover, 10 another part is received by the photodetecting element 8 mounted on the package 41 to obtain the tracking error detection signal and information reproduction 15 signal.

The principle of the present invention will 20 be described with reference to Fig. 5(a) to 5(e). Fig. 5(a) and 5(b) are the optical path from the light source of the optical head to the focusing lens according to this embodiment shown in Fig. 1, which are sectional views including the mount surface for the 25 laser chips 2 and substantial sectional views excluding the semiconductor mirror 5, mirror 11 and composite element 12. Fig. 5(a) shows the state where the semiconductor laser chips 4a and 4b are mounted

accurately facing to the direction of the optical axis 51. Three solid lines show the laser beam 6a emitted from the semiconductor laser chip 4a to reach the entrance pupil plane 52 of the focusing lens 13, and 5 particularly the central solid line 53a shows the central beam having the highest optical intensity. Three broken lines show the laser beam 6b emitted from the semiconductor laser chip 4b, and particularly the central solid line 53b shows the central beam having 10 the highest optical intensity. Since the semiconductor laser chip 4a is on the optical axis 51, the central beam 53a is incident to the center of the focusing lens 13. On the other hand, since the semiconductor laser chip 4b is outside the optical axis 51, the central 15 beam 53b, after going parallelly with the optical axis 51 to pass the collimating lens 10, meets the optical axis at a position equal to the focal distance of the collimating lens 10. Then, when the focusing lens 13 is arranged at the position where the central beam 53b 20 meets the optical axis 51, the highest optical efficiency for the both laser beams is obtained, and thus little change occurs in the optical efficiency even if the focusing lens 13 is moved to either direction for the tracking servo. However, angle 25 accuracy in mounting the laser chips is approximately ± 1 to ± 2 degrees. Fig. 5(b) shows the central beam 53a when the semiconductor laser chip 4a is mounted by tilting in the upward direction on the paper by θ_a

degrees and the central beam 53b when the semiconductor laser chip 4b is mounted by tilting in the downward direction on the paper by θ_b degrees. Presuming that the tilt angle of the semiconductor laser chips 4a is
5 θ_a , the tilt angle of the semiconductor laser chips 4ba is θ_b and the focal distance of the collimating lens 10 is f_c , the central beam 53a separates from the optical axis 51 upward by $f_c * \theta_a$, and the central beam 53b separates from the optical axis 51 downward by $f_c * \theta_b$.
10 presuming $f_c = 20$ mm, $\theta_a = 2$ degrees and $\theta_b = 2$ degrees, the gap between the central beam 53a and the central beam 53b becomes about 1.4 mm. If the focusing lens 13 is adjusted such that its central position meets the position of the central beam 53a in assembling the
15 optical head, the optical intensity distribution of the laser beam 6a that is incident to the focusing lens 13 becomes centrosymmetrical as shown by the contour 54a of Fig. 5(c). Accordingly, little change occurs in the optical efficiency even if the focusing lens 13 is moved to either direction, as shown by the solid line
20 55a of Fig. 5(e), little change occurs in a recording power when the tracking servo is executed, and thus a stable recording can be achieved. On the other hand, since the entrance pupil diameter of the focusing lens
25 13 is approximately 4 mm, the central beam 53b of the laser beam 6b is off remarkably from the center of the focusing lens 13. Thus, the optical intensity distribution of the laser beam 6b becomes asymmetrical

in the upward/downward directions on the paper as shown by the contour 54b of Fig. 5(c). If the focusing lens 13 is moved in the upward/downward direction on the paper of Fig. 5(d) for the tracking servo, the optical efficiency changes asymmetrically relative to the movement of the focusing lens 13 as shown by the dotted line of Fig. 5(e), and thus the stable information recording is difficult due to the fluctuation of the recording power. In the present invention, the tracking servo direction 14 is in the right and left direction on the paper of Fig. 5(d), there is little change of the optical efficiency relative to the movement of the focusing lens 13, and thus the stable information recording with little change of the recording power can be achieved.

A second embodiment of the present invention will be described by using Fig. 6 to Fig. 9. Fig. 6 shows the constitution of the optical disk unit and the optical head using the present invention. Hereinafter, the parts with the same reference numeral as the first embodiment have the same function, and description of the function of these parts will be omitted. Reference numeral 61 denotes a semiconductor plate where the photodetecting element, the electronic circuit and the like are formed and the laser chips and the like are mounted thereon. Similarly to the semiconductor plate 1 of Fig. 1, the front surface cannot be seen actually because it is arranged facing its rear surface to a

viewer, but the drawing shows in the phantom state where the plate is seen from the rear surface to the front surface. 62 denotes the mount surface for the laser chips, which is parallel with the surface of the 5 semiconductor plate 61. The arrow 63 shows the normal direction of the mount surface for the laser chips 2. Similarly to the first embodiment, 4a denotes the semiconductor laser chip for the DVD, and 4b denotes the semiconductor laser chip for the CD-R. The 10 semiconductor laser chips 4a and 4b are adhered on the mount surface for the laser chips by soldering or the like. 65 denotes the semiconductor mirror surface. The laser beam 66a for the DVD, after radiated from the semiconductor laser chip 4a to the left direction on 15 Fig. 6 (the radius direction 18 of the recording medium in Fig. 6), is reflected by the semiconductor mirror surface 65, and becomes the parallel luminous flux by the collimating lens 10. The laser beam 66b for the CD-R, after radiated from the semiconductor laser chip 20 4b to the left direction on Fig. 6 (the radius direction 18 of the recording medium in Fig. 6), is also reflected by the semiconductor mirror surface 65, and becomes the parallel luminous flux by the collimating lens 10. 67 denotes the photodetecting 25 element that obtains the focusing error detection signal, 68: the photodetecting element that obtains the tracking error detection signal and the information reproduction signal, 69: photodetecting element that

monitors the light emission amount of the semiconductor laser chips 4a and 4b, and 67, 68 and 69 are severally formed on the surface of the semiconductor plate 61.

11 denotes the mirror that radiates the laser beams 66a and 66b on an information medium. 12 denotes the composite element in which a polarization four-division grating and a quarter-wave plate are adhered into a unit, 13: the focusing lens, 15: the optical disk for the DVD and optical disk for the CD-R and CD, 16: the 5 rotation center of the optical disk 15, the circle 17 in a dotted line show the track to which information is recorded, 18: the radius direction of the optical disk 15, and 14: the tracking servo direction, which severally perform the same function as the composite 10 element of the first embodiment. In this embodiment, the projected image in the tracking servo direction is reflected by the mirror 71 and the semiconductor mirror 65 to unify the normal direction 63 of the mount 15 surface for the laser chips 62. Specifically, the 20 mount surface for the laser chips 62 for mounting the semiconductor laser chips 4a and 4b is substantially perpendicular to the tracking servo direction 14. The characteristic of the second embodiment comparing to the first embodiment is that the laser beam 66a and 66b 25 are incident from the disk circumference direction, which is perpendicular to the disk radius direction 18, to the mirror 71, and that the arrangement of the semiconductor plate 61 is rotated for 90 degrees from

that of the semiconductor plate 1 for this purpose so
that the semiconductor laser chip 4a and the
semiconductor laser chip 4b are arranged in the optical
head thickness direction (the vertical direction on the
5 paper). These characteristics can be similarly
realized if, for example, another mirror is inserted
between the collimating lens 10 and the mirror 71 to
make the laser beams 66a and 66b to be incident from
the disk radius direction 18.

10 Fig. 7(a) shows the surface of the
semiconductor plate 61 as seen from the collimating
lens side. The eight pieces of quarter circles painted
in black shown by the reference numeral 72a show the
laser beams of the wavelength λ_a , which are separated
15 by the grating of the composite element 12, and the
eight pieces of quarter circles that are not painted
shown by the reference numeral 72b show the laser beams
of the wavelength λ_b , which are separated by the
grating of the composite element 12. 67 denotes the
20 photodetecting element for obtaining the focusing error
detection signal, and it receives the laser beams 72a
of the wavelength λ_a and the laser beams 72b of the
wavelength λ_b . The knife edge method (Foucault method)
by the four-division beams is used similarly to the
25 first embodiment, a signal for subtraction is obtained
from the A terminal and the B terminal of the wire
bonding pad 74 when the photodetecting elements are
connected by the conductive thin film 73 such as

aluminum as shown in Fig. 7. The photodetecting elements shown by the reference numeral 68 in Fig. 6 for obtaining the tracking error detection signal and the information reproduction signal is constituted by 5 68a and 68b in detail. 68a denotes four photodetecting elements for receiving the laser beam 72a, and the 68b denotes four photodetecting elements for receiving the laser beam 72b. The output signal of the photodetecting elements 68a and 68b is input to the 10 amplifier 75 formed on the semiconductor plate. The amplifier 75 outputs the signal of the photodetecting elements 68a to the D, E, F and G terminals of the pad 74 when the semiconductor laser chip 4a emits light, and outputs the signal of the photodetecting elements 15 68b to the D, E, F and G terminals of the pad 74 when the semiconductor laser chip 4b emits light. The photodetecting elements 67 of this embodiment can be commonly used by the beams with the different wavelengths, and the photodetecting elements 68 and the 20 amplifiers 75 of this embodiment can be commonly used by the beams with the different wavelengths. Thus, not only the surface of the semiconductor plate 1 can be saved, but also the number of the wire bonding pads and the output wires can be reduced, which is effective in 25 making the size of the package that encloses the semiconductor plate 1 smaller.

Fig. 7(b) shows a section structure of the semiconductor plate 61 at the dotted line A-A' of Fig.

7(a). Although it is preferable that the semiconductor mirror 65 is formed at the angle of 45 degrees to the mount surface for the laser chips 62, there are cases where the semiconductor mirror 65 is off from 45
5 degrees and where the emission direction of the laser beams 66a and 66b is off from the perpendicular direction of the semiconductor plate 61.

Fig. 8(a) shows the structure of the package 81 enclosing the semiconductor plate 1, Fig. 8(b) shows 10 the sectional view at the broken line B-B'. 82 are the lead wires connected with the pad 74 of the semiconductor plate 61 with the bonding wires. The surface of the base 83 where the semiconductor plate 61 is mounted is tilted such that the emission direction 15 of the laser beams 66a and 66b becomes perpendicular to the glass cover 84. As described in the description of the first embodiment, even if the laser beams to be radiated are not perpendicular to the glass cover 84, they may be constituted so as to be parallel with the 20 optical path irradiated substantially perpendicular to the optical disk to be irradiated. 84 denotes the glass cover for closing the semiconductor plate 61, and the reflection plane 85 is provided inside the glass cover 84 for reflecting the peripheral portion of the 25 laser beams 66a and 66b. The photodetecting element 69 of the semiconductor plate 61 receives the reflected beam by the reflection plane 85 to obtain a signal for monitoring the emission amount of the semiconductor

laser chips 4a and 4b.

Fig. 11(a) and 11(b) show the structure of the optical disk unit using the second embodiment of the present invention, in which 11(a) is a plan view and 11(b) is a side view. 111 denotes the case of the optical disk unit. 112 denotes the motor mounted on the case 111 of the optical disk unit to rotate the optical disk 15 via the shaft 103. 114 denotes the optical head where the package 81 enclosing the semiconductor plate 61 and the lens actuator 115 mounted with the focusing lens 13 are mounted. 106 denotes the access mechanism mounted on the optical head 114, and 107 denotes the rail mounted on the case 111 of the optical disk unit. The optical head 114 can move on the rail 107 by the access mechanism 116 in the radius direction of the disk 15. The collimating lens 10, the mirror 71 and the composite element 12 are inside of the optical head 114. The laser beam 66a or 66b radiated from the semiconductor laser chip 4a or 4b mounted on the package 81 is radiated from the optical head 114 via the focusing lens 13 on the lens actuator 115, and radiated on the rotating optical disk 15. The reflected beam is incident to the optical head 114 via the focusing lens 13 again, a part of which is received by the photodetecting element 67 mounted on the package 81 to obtain the focusing error detection signal. Moreover, another part is received by the photodetecting element 68 mounted on the package 81 to

obtain the tracking error detection signal and information reproduction signal.

Fig. 9(a) and 9(b) show the structure of the lens actuator used in this embodiment. Fig. 9(a) is a plan view as seen from the direction of the optical disk 15. 91 denotes the lens holder that mounts the focusing lens 13 and the coil 94, and is held by the holding block 93 by the spring 92. The magnet is next to the spring 92, and the magnet 95b and the holding block 93 are fixed to the optical head case. When a current is supplied to the coil 94, the electromagnetic force generated between the coil 94 and the magnet 95 makes the lens holder 91 move to the vertical direction on the paper, and thus the tracking servo can be performed. In the lens actuator of this kind, its dimensions become long from the focusing lens 13 to the holding block. On the other hand, in Fig. 1 and Fig. 6, since a motor (not shown) and the like are under the rotation center of the optical disk 15 for rotating the optical disk 15, the lens actuator is arranged such that the rotation center 16 of the optical disk 15 is positioned in the upper position on the paper taking into consideration that the optical head moves in the inner circumference of the optical disk 15.

Fig. 9(b) is a sectional side view of the lens actuator as seen from the horizontal direction. The solid line 97 shows the surface of the optical head case where the magnet 95, the holding block 93 and the

like are fixed. The lens holder 91 is light weight and has the box structure to increase the rigidity of the portion holding the focusing lens 13. Particularly, the side plate portion 96 is necessary to increase the 5 rigidity. The constitution is made such that the laser beams 66a and the 66b are incident from the right direction on the paper of Fig. 9(a) and 9(b), that is, the disk circumference direction perpendicular to the disk radius direction, and are reflected by the mirror 10 71. Accordingly, in the second embodiment, the optical head and the optical disk unit can be made thin comparing to the first embodiment.

In this embodiment shown in Fig. 6, since the tracking servo direction 14 is substantially unified 15 with the normal direction 63 of the mount surface for the laser chips 62, there is smaller change of the optical efficiency relative to the moving direction of the focusing lens as shown in Fig. 5(e), and thus the recording power reduces and the stable information 20 recording can be achieved.

As described above, according to the present invention, in the laser module for recording information to the optical information medium or reproducing the information by using a plurality of the 25 laser beam sources, the optical head including the laser module, or the optical information recording and reproduction apparatus that mounts the optical head, the laser module, the optical head or the optical

information recording and reproduction apparatus can be realized in which the reduction and the change of the optical efficiency of each laser beam is small relative to the angle shift occurred during mounting the 5 semiconductor laser chip and the movement of the focusing lens for the tracking servo.

INDUSTRIAL APPLICABILITY

As described above, the laser module, the optical head or the optical information recording and 10 reproduction apparatus according to the present invention is effective for the light source having the laser beams with a plurality of different wavelengths. Thus, the light source is made to be a module, and it is possible to provide the optical head to which the 15 light source as the module is assembled with high accuracy and the apparatus that records/reproduces the information by using the optical head with any of a plurality of the wavelengths.

CLAIMS

1. An optical information recording and reproduction apparatus, comprising:

a setting portion of an optical information

5 medium;

a light source where a plurality of semiconductor laser chips are mounted on a surface;

optical convergence means for converging each of a plurality of laser beams radiated from each of
10 laser chips into an optical spot on said optical information medium when the optical information medium is set to said setting portion; and

tracking servo means for moving the optical convergence means in a tracking servo direction
15 perpendicular to a track direction such that the optical spot accurately scans the track of the optical information medium,

wherein the surface on which a plurality of the semiconductor laser chips are mounted is
20 substantially perpendicular to the tracking servo direction.

2. An optical information recording and reproduction apparatus that comprises: a first reflection plane that reflects the laser beams radiated
25 from each of a plurality of the semiconductor laser chips; and a second reflection plane that guides the laser beams from the first reflection plane to the optical convergence means,

wherein the first reflection plane is formed on the same plate as the mount surface for the laser chips.

3. An optical information recording and
5 reproduction apparatus according to Claim 2,

wherein the laser beams from the first reflection plane is made to be incident from the tracking servo direction to the second reflection plane, and

10 a plurality of the semiconductor laser chips are arranged in an inner plane direction parallel to an optical information medium plane.

4. An optical information recording and
reproduction apparatus according to Claim 2,

15 wherein the laser beams from the first reflection plane is made to be incident from the track direction to the second reflection plane, and

a plurality of the semiconductor laser chips are arranged in an inner plane direction perpendicular
20 to the optical information medium plane.

5. An optical information recording and
reproduction apparatus according to Claim 1,
wherein photodetecting elements for receiving
each of a plurality of the laser beams radiated from
25 each of the laser chips are provided on a surface where
said laser chips are mounted.

6. An optical head used in an optical
information recording and reproduction apparatus that

performs tracking servo to record and reproduces information when an optical spot is radiated on an optical information medium,

wherein the optical head comprises: a light source on which each of semiconductor laser chips having a plurality of wavelengths is mounted on a surface; and optical convergence means for converging each of a plurality of laser beams radiated from each of the laser chips on said optical information medium as the optical spot, and the surface where a plurality of the semiconductor laser chips are mounted is substantially perpendicular to said tracking servo direction.

7. An optical head according to Claim 6,
15 comprising:

a first reflection plane for reflecting the laser beam radiated from each of a plurality of the semiconductor laser chips; and

a second reflection plane for guiding the laser beam from the first reflection plane to the optical convergence means, wherein the first reflection plane is formed on a plate same as the mount surface for the laser chips.

8. An optical information recording and reproduction apparatus according to Claim 7,
25 wherein the laser beams from the first reflection plane is made to be incident from the tracking servo direction to the second reflection

plane, and

a plurality of the semiconductor laser chips are arranged in an inner plane direction parallel to an optical information medium plane.

5 9. An optical information recording and reproduction apparatus according to Claim 7,

wherein the laser beams from the first reflection plane is made to be incident from the track direction to the second reflection plane, and

10 a plurality of the semiconductor laser chips are arranged in an inner plane direction perpendicular to the optical information medium plane.

10. An optical information recording and reproduction apparatus according to Claim 6,

15 wherein a photodetecting element for receiving each of a plurality of the laser beams radiated from each of the laser chips is provided on a surface where said laser chips are mounted.

11. A laser module used for an optical head 20 constituting an optical information recording and reproduction apparatus, which performs tracking servo to record and reproduce the information when an optical spot is radiated on an optical information medium, and including optical convergence means for converging 25 laser beams into the optical spot on said optical information medium, the laser module, comprising:
a light source where each of semiconductor laser chips having a plurality of wavelengths is

mounted on its surface;

a photodetecting element for receiving each of a plurality of the laser beams radiated from each of the laser chips; and

5 a package for enclosing said light source and said photodetecting element, wherein the surface where a plurality of the semiconductor laser chips are mounted is substantially perpendicular to said tracking servo direction.

10 12. A laser module, comprising:

 a semiconductor plate;
 a mount surface for laser chips provided on the semiconductor plate;

 a plurality of semiconductor laser chips
15 mounted on the mount surface for the laser chips;

 a reflection plane provided on the semiconductor plate for reflecting laser beams radiated from a plurality of the semiconductor laser chips; and
 a photodetecting element, which is provided

20 on the semiconductor plate, for receiving the laser beams radiated from a plurality of the semiconductor laser chips,

 wherein the photodetecting elements are arranged at both sides of a plurality of the
25 semiconductor laser chips in a direction where a plurality of the semiconductor laser chips are arranged.

13. A laser module according to Claim 12,

comprising:

a package for enclosing the semiconductor plate, wherein the outline of the package in a plane perpendicular to a direction, where the laser beam is
5 radiated from the package, has an approximate rectangular shape in a degree where its long direction and short direction can be distinguished, and a plurality of semiconductor laser chips and the photodetecting element are arranged in a direction of
10 the short side of the package.

14. A laser module, comprising:

a semiconductor plate;
a mount surface for laser chips provided on the semiconductor plate;

15 a plurality of semiconductor laser chips mounted on the mount surface for the laser chips; a reflection plane provided on the semiconductor plate for reflecting laser beams radiated from a plurality of the semiconductor laser chips; and

20 a photodetecting element, which is provided on the semiconductor plate, for receiving the laser beams radiated from a plurality of the semiconductor laser chips,

wherein the semiconductor plate includes a
25 plurality of pads for electrically connecting with an external electronic circuit and a plurality of the pads are arranged along a side of the semiconductor plate parallel with a direction where a plurality of the

semiconductor laser chips are arranged.

15. A laser module according to Claim 14,
comprising:

a plurality of the lead wires for
5 electrically connecting a package for enclosing the
semiconductor plate with an external electronic
circuit, wherein the outline of the package in a plane
perpendicular to a direction, where the laser beam is
radiated from the package, has the approximate
10 rectangular shape in a degree where its long direction
and short direction can be distinguished, and a
plurality of the lead wires are arranged in a direction
of the short side of the package.
